

Endometriosis Treatment

Endometriosis is a condition where tissue grows in places where it shouldn't, such as the ovaries and fallopian tubes.

This causes severe pelvic pain that often intensifies during menstrual periods. Symptoms can start with a person's first period and persist until menopause, severely impacting quality of life.

Endometriosis Symptoms include:

- Excess menstrual bleeding
- Abdominal pain and swelling
- Lower back pain
- Pain during and after intercourse
- Infertility
- Constipation
- Weight gain

The only definitive way to diagnose endometriosis is through a laparoscopy, a minimally invasive surgery performed under general anaesthesia. This procedure not only confirms the diagnosis but also allows for the treatment of endometrial tissue, offering significant relief from symptoms and improving the chances of pregnancy.
